Unlike Project Gutenberg, which gives all books equal billing, books on Amazon Cheap Reads are organized by rating to help the cream rise to the surface. However, five stars aren't necessarily a guarantee of quality; many books only have one or two reviews, and some authors are known to rope in friends and family to leave positive feedback.

In general terms, neurotransmitters can be considered excitatory since they increase the chances of the postsynaptic neurone firing action potentials or inhibitory as they decrease the chances of this process occurring. The importance of this for overall neurone functioning is illustrated in the next video step.

Neurotransmission - Good Brain, Bad Brain: Basics

At its simplest, the process of neurotransmission consists of invasion of a nerve terminal by an action potential, fusion of one or more vesicles with the presynaptic membrane, release of a few thousand molecules of one chemical substance into a synaptic cleft, stimulation of a single population of postsynaptic receptors located within that synapse, and the rapid elicitation of an excitatory or inhibitory postsynaptic potential due to the opening of ion channels on the postsynaptic membrane.

The human brain has billions of neurons and these neurons communicate through each other through chemical signals. This transfer of information from one neuron to another through chemical signals is called neurotransmission.

Understanding the principles of chemical neurotransmission is a fundamental requirement for grasping how psychopharmacologic agents work, because they target key molecules involved in neurotransmission. Drug targeting of specific chemical sites that influence neurotransmission is discussed in Chapters 2 and 3.

Scientists Say: Neurotransmitters When an electrical signal reaches the end of a neuron, it triggers the release of tiny sacs that had been inside the cells. Called vesicles, the sacs hold chemical messengers such as dopamine (DOAP-uh-meen) or serotonin (Sair-uh-TOE-nin).

Neurotransmission provides a variety of potential targets for neurotoxicants, including enzymes involved in neurotransmitter synthesis, mechanisms of neurotransmitter storage and release, enzymes or uptake systems involved in neurotransmitter removal, or receptors and their coupled signal transduction systems. Domoic acid, discussed in this article as a neuronopathic compound, is an example of these chemicals, as it activates certain subtypes of receptors for the excitatory neurotransmitter ...

Neurotransmitters are substances which neurons use to communicate with one another and with their target tissues in the process of synaptic transmission (neurotransmission). Neurotransmitters are synthesized in and released from nerve endings into the synaptic cleft.

Description. Neurotransmission is the second volume of the proceedings of the Sixth International Congress of Pharmacology, organized by the Finnish Pharmacological Society and held in Helsinki, Finland, on July 20-25, 1975. The papers focus on the developments in neurotransmission and cover topics ranging from novel transmitter substances and extraneuronal uptake of catecholamines to axonal transport mechanisms and nerve growth factor.

In a technical tour de force, we have created a framework demonstrating the underlying fundamental principles of bidirectional coupling of neuronal and neurotransmitter dynamical systems. Specifically, in the present study, we combined multimodal neuroimaging data to causally explain the functional effects of specific serotonergic receptor (5-HT_{2A}R) stimulation with psilocybin in healthy humans.
